

Derivation of Leaching fraction calculation including rainfall

The Leaching Fraction (LF) equation used in the calculation of Nitrate -nitrogen loading to the ground water is:

$$LF = \frac{[C_{li} * ET - C_{lc} - V_r(C_{li} - C_{lr})]}{[E_t * C_{lp} - C_{lc} - V_r * (C_{li} - C_{lr})]}$$

Where:

LF= Leaching Fraction.

ET= Seasonal evapotranspiration (kg/ha).

C_{li}= Chloride concentration in the irrigation water (mg/l)

C_{lp}= Chloride concentration in the percolating water below the crop root zone (mg/l).

C_{lc}= Amount of chloride taken up by the crop (kg/ha).

V_r=volume of rainfall Kg/ha

C_{lr}= chloride of rainfall(mg/l)

The equation is derived using the definition of leaching fraction and the mass balance equation for chloride

The Leaching Fraction (LF) is defined as:

$$LF = \frac{V_p}{V_i + V_r} \dots (1)$$

where:

V_p: Volume of percolating water below the crop root zone (l).

V_i: Volume of irrigation water

V_r Volume of rainfall or water supplied from a second source of irrigation water. (i.e. surface water source 1 ground water source 2 both having different chloride content)

Volume of the irrigation plus rainfall is:

$$V_r + V_i = V_p + ET$$

$$V_i = V_p + ET - V_r \dots (2)$$

where ET is seasonal evapotranspiration (l)

Substituting eq.2 into eq. 1 and solving for V_p results in eq 3.

$$V_p = \frac{LF * ET}{1 - LF} \dots (3)$$

**By Mass balance under steady state conditions, the chloride input equals the chloride output
input=output**

$$C_{li} * V_i + C_{lr} * V_r = C_{lp} * V_p + C_{lc} \dots (4)$$

Substitute eq 2 into 4 and solve for V_p

$$C_{li}(V_p + ET - V_r) + C_{lr} * V_r = C_{lp} * V_p + C_{lc}$$

$$C_{li} * V_p + C_{li} * ET - C_{li} * V_r + C_{lr} * V_r = C_{lp} * V_p + C_{lc}$$

$$C_{li} * V_p - C_{lp} * V_p = C_{lc} - C_{lr} * V_r + C_{li} * V_r - C_{li} * ET$$

$$V_p = \frac{C_{lc} - C_{lr} * V_r + C_{li} * V_r - C_{li} * ET}{C_{li} - C_{lp}} \dots (4)$$

Take eq. 3 and substitute into equation 4

$$LF \cdot ET / (1 - LF) = Clc - Clr \cdot Vr + Cli \cdot Vr - Cli \cdot Et / (Cli - Clp)$$

$$:LF \cdot Et (Cli - Clp) = (1 - LF)(Clc - Clr \cdot Vr + Cli \cdot Vr - Cli \cdot Et)$$

$$(LF \cdot Et \cdot Cli) - (LF \cdot ET \cdot Clp) = Clc - (LF \cdot Clc) - (Clr \cdot Vr) + (LF \cdot Clr \cdot Vr) + (Cli \cdot Vr) - (LF \cdot Cli \cdot Vr) - (Cli \cdot Et) + (LF \cdot Cli \cdot ET)$$

Simplify remove left and right side $LF \cdot Et \cdot Cli$

$$- (LF \cdot ET \cdot Clp) = Clc - (LF \cdot Clc) - (Clr \cdot Vr) + (LF \cdot Clr \cdot Vr) + (Cli \cdot Vr) - (LF \cdot Cli \cdot Vr) - (Cli \cdot Et) + (LF \cdot Cli \cdot ET)$$

move terms with Lf on left side

$$- (LF \cdot ET \cdot Clp) + (LF \cdot Clc) - (LF \cdot Clr \cdot Vr) + (LF \cdot Cli \cdot Vr) = Clc - (Clr \cdot Vr) + (Cli \cdot Vr) - (Cli \cdot Et)$$

$$Lf(-ET \cdot Clp + Clc - (Clr \cdot Vr) + (Cli \cdot Vr)) = Clc + Vr(Cli - Clr) - Cli \cdot Et$$

$$LF = Clc + Vr(Cli - Clr) - Cli \cdot ET / (Cli \cdot Vr) - (Clr \cdot Vr) - ET \cdot Clp + Clc$$

Multiple numerator and denominator by - sign

$$LF = Cli \cdot ET - Clc - Vr(Cli - Clr) / Et \cdot Clp - Clc - Vr \cdot (Cli - Clr) \dots \text{eq. 5}$$

$$LF = [Cli \cdot ET 10^{-6} - Clc - Vr(Cli - Clr) 10^{-6}] / [Et \cdot Clp 10^{-6} - Clc - Vr \cdot (Cli - Clr) 10^{-6}] \dots \text{eq. 6}$$

ET and Vr and Clc in units of Kg/ha and Cli, Clr, and Clp are in units of (mg/l)
